

Rudolf E. Kalman's quest for algebraic characterizations of positivity

Tryphon T. Georgiou*

** University of California, Irvine (e-mail: tryphon@uci.edu).*

Abstract: The present paper is a tribute to Professor Rudolf Emil Kalman, father of Mathematical System Theory and a towering figure in the field of Control and Dynamical Systems. Amongst his seminal contributions was a series of results and insights into the role of positivity in System Theory and in Control Engineering. The paper contains a collection of reminiscences by the author together with brief technical references that touch upon the unparalleled influence of Professor Kalman on this topic.

Keywords: Rudolf E. Kalman

1. THE EARLY YEARS

The miracle years for Rudolf Kalman began in 1957, one year before he submitted his doctoral dissertation on the subject of sampled data systems. A constant stream of original ideas began pouring out, ideas that were to transform the field of control, educate and inspire generations of theorists, and enable transformative new technologies. Chief among those was the Kalman filter, published in Kalman [1960], a most impactful contribution that is ubiquitous in today's technological advances, from guidance and navigation systems, cellphones, industrial controls to radar technology and vision systems. But of no lesser importance were his insights and parallel contributions to algebraic structure of dynamical systems, optimization, sampled data controls, and stability theory. The latter subject is intrinsically connected with positivity and passivity, concepts that were central to his thinking throughout his life.

His first paper on "Physical and mathematical mechanisms of instability in nonlinear automatic control," published in Kalman [1957], became very influential in the subsequent development of absolute stability theory (see Liberzon [2006]) and the topic never ceased to excite his interest and creativity. Shortly afterwards, in 1963, he published his work on Lyapunov functions for the Lur'e problem, Kalman [1963] inspired by Yakubovich [1962]. This work brought to life the so-called Kalman-Yacubovich-Popov (KYP) lemma that highlighted the centrality of passivity theory and was a harbinger of a great many developments that took place in the subsequent years until the present (Iwasaki and Hara [2005], Rantzer [1996]). The KYP lemma proved the entry point for linear matrix inequalities and convex optimization in control theory (Willems [1971]) and of key importance in filtering, stochastic realizations, control design, circuit theory as well as in addressing Kalman's far reaching question on the inverse regulator problem (Kalman [1964]).

Moving forward, Kalman explored this circle of ideas in providing characterizations of stability with respect to more general algebraic domains (Kalman [1965, 1969])

via conditions that capture positivity in a suitable sense. When reading these works, the converse question of characterizing domains via linear matrix inequalities is inescapable.

2. POST 1970

A duality between quadratic regulator theory and stochastic realization theory, expanded upon and summarized in P. Faurre's 1972 dissertation (cf. Faurre et al. [1978]), played a key role in Kalman's thought during the following years. Pursuing leads in early work by K. Löwner, Kalman sought to obtain an algebraic characterization of minimal stochastic partial realizations (unpublished notes by Kalman). An alternative form of the same problem amounts to realizing a circuit with a minimal number of passive elements (more accurately, minimal McMillan degree) based on the value of its impedance at specified complex frequencies. Potential leads were sought in invariants of linear quadratic problems – a subject of conversation between the late E. Bruce Lee and Kalman during the "1975 Birch Island Conference on Systems Theory" in Bruce's cabin (Figure 1).

The topic of "positive linear systems" remained a focus in his research proposals, motivated by applications to circuits and modeling of random signals. However, paraphrasing his words, progress was frustratingly slow. In a 1976 final progress report to AFOSR he highlighted the apparent difficulties in dealing with the "interaction between positive and algebraic." At that point, in the report, he declared that "no further work on this topic is planned in the near future." But those who knew Kalman, knew better, that he never gives up. Soon afterwards in "Realization of covariance sequences," Kalman [1982], he sought an answer in the form of algebraic inequalities in terms of Schur parameters.

His insights pointed to computational algebraic geometry which, however, didn't seem to have reached a satisfactory stage at the time for the sought purpose. The same seemed true for classical decision theory, in the style of Tarski and Seidenberg. Under his direction, I began working

on my dissertation on this topic in 1981. Early on my dear friend Pramod Khargonekar joined me on this, and together we worked through the classical literature on the moment problem (Georgiou and Khargonekar [1982]). Yet the “interaction between positive and algebraic” seemed once again a roadblock towards the type of invariants that Kalman sought. One more year went by before I saw how to characterize realizations of a fixed McMillan degree by topological methods (see Georgiou [1983, 1987b,a]). I recall with a mix of nostalgia my last years in Gainesville and all the ups and downs during the final stretch. My interactions with Kalman were points of inspiration as well as contention, due to differing views on the nature of the problem. While the sequel of Kalman’s problem on partial realization of covariance sequences proved especially fruitful (see Byrnes et al. [1995], Byrnes and Lindquist [1997], Georgiou [1999], Byrnes et al. [2001, 2006]), Kalman’s vision of an *algebraic* characterization was never fully accomplished. It is the sincere hope of the author that the present paper serves as a motivation and a challenge to others to attempt the next steps. Kalman’s dream and quest live on.
